

It looks like you've hit a bit of a "chicken and egg" problem. Your system is trying to use an HTTPS repository for Brave, but it's missing the `apt-transport-https` package. When you try to install that package, your system is failing to connect to the mirror (`ftp.sjtu.edu.cn`), likely due to a temporary network issue with that specific server or a localized DNS problem.

Since you're on Linux Mint, we can fix this by temporarily switching to a more reliable mirror and manually grabbing the necessary transport package.

1. Fix the Repository Mirror

The error shows your system is trying to reach a mirror in China (`sjtu.edu.cn`), which might be slow or unstable from your location. Let's switch back to the default or a closer mirror.

- Open **Software Sources** from your application menu.
- Under **Official Repositories**, click on the URLs for "Main" and "Base".
- Click **"Restore default settings"** or select a mirror that shows the highest speed in the speed test.
- Click **OK** and let it refresh the cache.

2. The Backslash Issue

Looking at your error message:

```
E: The method driver /usr/lib/apt/methods/\https could not be found.
```

There is a literal **backslash** (`\`) before `https` . This usually happens if there was a typo when copy-pasting the `echo` command in Step 3. Let's clean that up first:

```
bash

sudo rm /etc/apt/sources.list.d/brave-browser-release.list
```

3. Install the Transport Package First

Before adding Brave again, ensure your system can actually handle HTTPS sources. Try installing the requirements again now that you've updated your mirrors:

```
bash

sudo apt update
sudo apt install apt-transport-https ca-certificates -y
```

4. Re-run the Brave Installation (Clean Version)

Now, let's run the steps again, but I've cleaned up the formatting to ensure no rogue backslashes enter your source file:

Step A: Add the Key

```
bash
```

```
sudo curl -fsSLo /usr/share/keyrings/brave-browser-archive-keyring.gpg https://brave-browser-apt-release.s3.brave.com/brave-browser-archive-keyring.gpg
```

Step B: Add the Repository (This is one single command)

```
bash
```

```
echo "deb [signed-by=/usr/share/keyrings/brave-browser-archive-keyring.gpg] https://brave-browser-apt-release.s3.brave.com/ stable main" | sudo tee /etc/apt/sources.list.d/brave-browser-release.list
```

Step C: Update and Install

```
bash
```

```
sudo apt update  
sudo apt install brave-browser -y
```

Why did this happen?

In Linux Mint (and Ubuntu-based systems), older versions required `apt-transport-https` to talk to any URL starting with `https://`. Most modern versions have this built-in, but if your initial install was minimal or the configuration file got a typo (like that `\https`), the system gets confused and looks for a driver that doesn't exist.

If the `sudo apt update` still fails after switching mirrors, would you like me to help you check your `/etc/apt/sources.list` file for any other syntax errors?
